Recap: Week 2

- Introduced the Kepler problem
 - Non-dimensionalisation simplified the formulation.
- Introduced the centered-difference
 approximation to overcome limitations
 of the scheme based on forward difference approximation (Euler).
 - Yields a new method, Verlet, which exhibits breath-taking accuracy for Keplerian orbits with nearconservation of total energy

How to step forward in time, given a gradient dr/dt?

- Euler: use forward difference approximation
 - The velocity at the current time step to extrapolate forward τ in time.
- Verlet (for solving a dynamics problem): use a centered difference approximation for the second derivative
 - So can use the acceleration and two previous values to make the update.

Time

Computational Physics: Lecture3

- Our last lecture on ODEs (PDEs from next week!)
- General form of ODEs suitable for numerical solution.
 - Dynamics equations we've considered so far are a special case (Verlet).
- Introduce Runge-Kutta (RK) (Taylor series) methods:
 - Can be applied to the general form for ODEs.
 - Euler's method is the first-order RK scheme.
- Simulate motion of a simple pendulum.
 - Illustrate the general form and a vector ODE right-hand side function.

General form of a system of ODEs

$$ullet rac{d\mathbf{x}}{dt} = \mathbf{f}\left[\mathbf{x}(t),t
ight].$$

- \bullet N coupled first order ordinary differential equations (ODEs).
- t is the *independent* variable (often time, but could be anything).
- \mathbf{x} is a vector of the dependent variables, $\mathbf{x}(t) = [x_1(t), x_2(t), \dots, x_N(t)]$.
- **f** is a vector function called the *right-hand side* (RHS):
 - $\mathbf{f}[\mathbf{x}(t),t] = \{f_1[\mathbf{x}(t),t], f_2[\mathbf{x}(t),t], \dots, f_N[\mathbf{x}(t),t]\}.$
- General Initial Value Problem (IVP):
 - Given $\mathbf{x}(t_1)$, calculate $\mathbf{x}(t)$ for $t > t_1$.
- Writing ODEs in this form makes it easy for us to apply general numerical methods
 - Just need to specify the RHS function $\mathbf{f}[\mathbf{x}(t), t]$.

Writing higher-order ODEs in general form

- A similar trick can get any high-order ODE into the general form
 - ? Where did we do this already?
- ullet Consider Nth-order linear ODE in y_1 : $a_1y_1+a_2rac{dy_1}{dt}+a_3rac{d^2y_1}{dt^2}+\cdots+a_{N+1}rac{d^Ny_1}{dt^N}=0$.
- We can always replace higher derivatives by new variables, y_2 , y_3 , ...:

$$ullet \quad y_2=rac{dy_1}{dt}\,,\quad y_3=rac{dy_2}{dt}=rac{d^2y_1}{dt^2}\,,\quad \cdots\quad y_N=rac{dy_{N-1}}{dt}=\left(rac{d}{dt}
ight)^{N-1}y_1\,.$$

• So now we can rewrite the Nth-order ODE equivalently in general form, $\frac{d\mathbf{x}}{dt} = \mathbf{f}$, by identifying:

$$ullet \mathbf{x}=(y_1,y_2,\ldots,y_N)$$
 , and $\mathbf{f}=\left[y_2,y_3,\ldots,-rac{1}{a_{N+1}}(a_1y_1+a_2y_2\cdots+a_Ny_N)
ight]$.

You need to know how to apply this procedure

Dynamics problems in general form

- Dynamics problems are a special case:
 - $\frac{d^2\mathbf{r}}{dt^2} = \mathbf{a}$ can be written $\frac{d\mathbf{r}}{dt} = \mathbf{v}$, $\frac{d\mathbf{v}}{dt} = \mathbf{a}$.
 - Position $\mathbf{r}=(x,y,z)$, velocity $\mathbf{v}=(v_x,v_y,v_z)$, and acceleration, $\mathbf{a}=(a_x,a_y,a_z)$.
- We can write them in the *general form*, $\frac{d\mathbf{x}}{dt} = \mathbf{f}(\mathbf{x},t)$, by identifying $\mathbf{x} = (x,y,z,v_x,v_y,v_z)^T$ and $\mathbf{f} = (v_x,v_y,v_z,a_x,a_y,a_z)^T$:

$$rac{d}{dt}egin{pmatrix} x\ y\ z\ v_x\ v_y\ v_z \end{pmatrix} = egin{pmatrix} v_x\ v_y\ a_z\ a_z \end{pmatrix} \,.$$

Euler's method for the general form

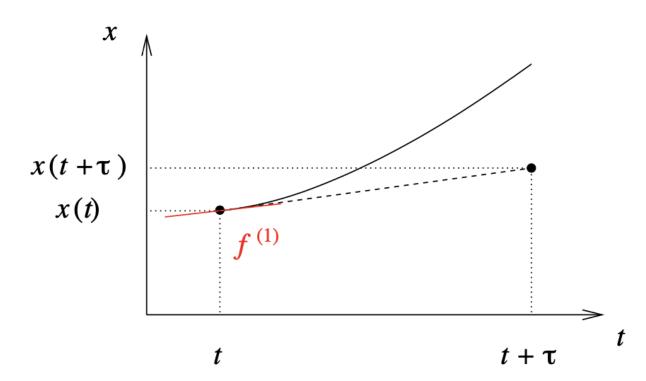

• Taylor-series expansion (using $\frac{d\mathbf{x}}{dt} = \mathbf{f}[\mathbf{x}(t), t]$):

$$egin{align} \mathbf{x}(t+ au) &= \mathbf{x}(t) + au rac{d\mathbf{x}}{dt} + O(au^2)\,, \ &= \mathbf{x}(t) + au \mathbf{f}[\mathbf{x}(t),t] + O(au^2)\,. \end{split}$$

- Euler's method matches the Taylor series to $O(\tau)$:
 - $\mathbf{x}(t+\tau) = \mathbf{x}(t) + \tau \mathbf{f}^{(1)}$, where $\mathbf{f}^{(1)} = \mathbf{f}[\mathbf{x}(t), t]$.
 - For Euler, $\mathbf{f}^{(1)}$ is the *right-hand side (RHS)* of the ODE.
- Euler for dynamics problems is a special case.

An Euler step in 1-D

- $ullet x(t+ au)=x(t)+ au f^{(1)}$,
- $f^{(1)}$ is $\frac{dx}{dt}$ evaluated at (t,x(t)):
 - the gradient of the tangent (red).
- Euler extrapolates forward τ along the tangent line.

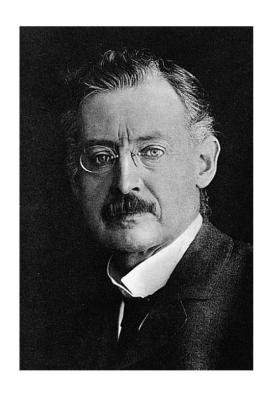

Testing Euler on a simple exponential case

- Simple ODE/IVP: $\dfrac{dx}{dt} = x$ with x(0) = 1 .
 - Analytic solution is $x(t) = e^t$ so integrating to t = 1 the final value should be $\approx 2.71828...$
- exp_euler solves this using Euler's method by defining a function rhs_exp(x) that returns the same input, x.
 - **?** Why is RHS $f^{(1)} = x$ here?
- Testing with exp_euler
 - Let's compute the error for a 10-step integration (dividing the unit interval into 10 steps).
 - ? What's your prediction for a 20-step integration...?
- Euler works ok, but can we do better than just taking little steps forward based on extrapolating the current derivative?

Runge-Kutta

- Carl Runge (1856-1927) and Martin Kutta (1867-1944).
- In general, we can do better than naively marching forward with a single estimate of the derivative by combining information at fractions of a step.

Runge-Kutta Methods

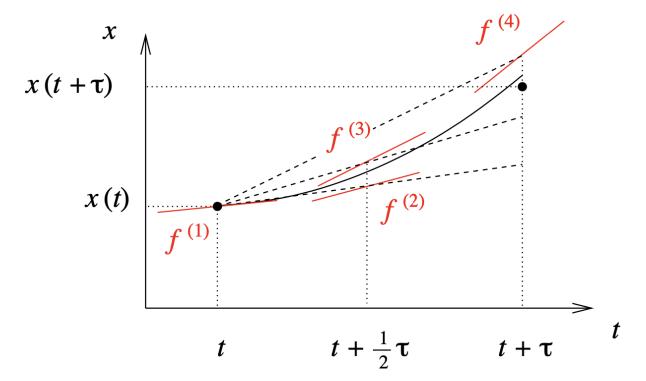

- Runge-Kutta methods match the Taylor series to a given order.
 - Euler is 'first-order Runge-Kutta': $\mathbf{x}(t+\tau) = \mathbf{x}(t) + \tau \mathbf{f}^{(1)}$.
- Higher-order schemes are more accurate.
- A very popular one: **☆ Fourth-Order Runge-Kutta (RK4) ☆**:

$$egin{aligned} \mathbf{x}(t+ au) &= \mathbf{x}(t) + rac{1}{6} au \left[\mathbf{f}^{(1)} + 2\mathbf{f}^{(2)} + 2\mathbf{f}^{(3)} + \mathbf{f}^{(4)}
ight] \,, \ \mathbf{f}^{(1)} &= \mathbf{f}[\mathbf{x}(t), t] \,, \ \mathbf{f}^{(2)} &= \mathbf{f}[\mathbf{x}(t) + rac{1}{2} au \mathbf{f}^{(1)}, t + rac{1}{2} au] \,, \ \mathbf{f}^{(3)} &= \mathbf{f}[\mathbf{x}(t) + rac{1}{2} au \mathbf{f}^{(2)}, t + rac{1}{2} au] \,, \ \mathbf{f}^{(4)} &= \mathbf{f}[\mathbf{x}(t) + au \mathbf{f}^{(3)}, t + au] \,. \end{aligned}$$

Fourth-Order Runge-Kutta (RK4)

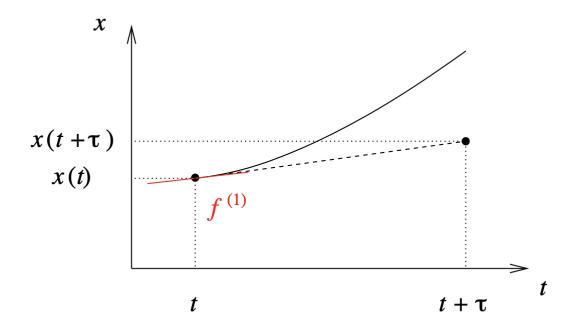

- Four RHS/gradient evaluations:
 - two at a half step $(t + \frac{1}{2}\tau)$
 - two at a full step $(t + \tau)$.
- Extrapolates forward to $t + \tau$ along a complicated average gradient line.

$$egin{aligned} \mathbf{x}(t+ au) &= \mathbf{x}(t) + rac{1}{6} au \left[\mathbf{f}^{(1)} + 2\mathbf{f}^{(2)} + 2\mathbf{f}^{(3)} + \mathbf{f}^{(4)}
ight] \,, \ \mathbf{f}^{(1)} &= \mathbf{f}[\mathbf{x}(t), t] \,, \ \mathbf{f}^{(2)} &= \mathbf{f}[\mathbf{x}(t) + rac{1}{2} au \mathbf{f}^{(1)}, t + rac{1}{2} au] \,, \ \mathbf{f}^{(3)} &= \mathbf{f}[\mathbf{x}(t) + rac{1}{2} au \mathbf{f}^{(2)}, t + rac{1}{2} au] \,, \ \mathbf{f}^{(4)} &= \mathbf{f}[\mathbf{x}(t) + au \mathbf{f}^{(3)}, t + au] \,. \end{aligned}$$

Euler (RK1)

$$\mathbf{x}(t+ au) = \mathbf{x}(t) + au \mathbf{f}^{(1)}$$
.

RK4

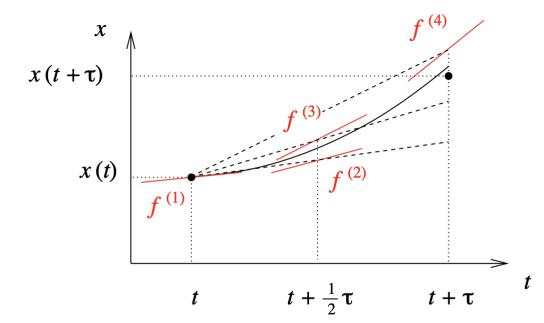

$$ullet \mathbf{x}(t+ au) = \mathbf{x}(t) + rac{1}{6} au\left[\mathbf{f}^{(1)} + 2\mathbf{f}^{(2)} + 2\mathbf{f}^{(3)} + \mathbf{f}^{(4)}
ight]$$

•
$$\mathbf{f}^{(1)} = \mathbf{f}[\mathbf{x}(t), t]$$

$$ullet \mathbf{f}^{(2)} = \mathbf{f}[\mathbf{x}(t) + rac{1}{2} au\mathbf{f}^{(1)}, t + rac{1}{2} au]$$

•
$$\mathbf{f}^{(3)} = \mathbf{f}[\mathbf{x}(t) + \frac{1}{2}\tau\mathbf{f}^{(2)}, t + \frac{1}{2}\tau]$$

•
$$\mathbf{f}^{(4)} = \mathbf{f}[\mathbf{x}(t) + \tau \mathbf{f}^{(3)}, t + \tau]$$

Understanding Runge-Kutta methods

- We're given a function, $\mathbf{f}[\mathbf{x}(t),t]$ and we have to try to work out how make a good step forward in time
- Consider a *Taylor-series expansion* of the dependent variables:

$$\bullet \quad \mathbf{x}(t+\tau) = \mathbf{x}(t) + \tau \frac{d\mathbf{x}}{dt} + \frac{\tau^2}{2!} \frac{d^2\mathbf{x}}{dt^2} + \frac{\tau^3}{3!} \frac{d^3\mathbf{x}}{dt^3} + \dots$$

- The Runge-Kutta approach is to reproduce this series to a certain order.
- Euler matches to first order (is 'RK1')
 - Uses RHS directly: $\frac{d\mathbf{x}}{dt} = \mathbf{f}\left[\mathbf{x}(t), t\right]$.
- Fourth-order Runge-Kutta (RK4) matches the Taylor series to $O(au^4)$.
 - i.e., local truncation error $O(au^5)$: very accurate
 - Very commonly used and can get you far: Matlab has RK4 ode45 (but we will write our own version 🐸)
- The derivation is complicated (cf. Appendix for RK2).

Code: Stepping with Euler

$$\mathbf{x}(t+ au) = \mathbf{x}(t) + au \mathbf{f}^{(1)}$$

```
for n in range(numSteps):
    # One step of Explicit Euler
    f = rhs_exp(x)
    x = x + tau * f
    t = t + tau
```

Code: stepping with RK4

$$\mathbf{x}(t+ au) = \mathbf{x}(t) + rac{1}{6} au\left[\mathbf{f}^{(1)} + 2\mathbf{f}^{(2)} + 2\mathbf{f}^{(3)} + \mathbf{f}^{(4)}
ight] \,,$$
 $\mathbf{f}^{(1)} = \mathbf{f}[\mathbf{x}(t), t] \,,$
 $\mathbf{f}^{(2)} = \mathbf{f}[\mathbf{x}(t) + rac{1}{2} au\mathbf{f}^{(1)}, t + rac{1}{2} au] \,,$
 $\mathbf{f}^{(3)} = \mathbf{f}[\mathbf{x}(t) + rac{1}{2} au\mathbf{f}^{(2)}, t + rac{1}{2} au] \,,$
 $\mathbf{f}^{(4)} = \mathbf{f}[\mathbf{x}(t) + au\mathbf{f}^{(3)}, t + au] \,.$

for n in range(numSteps):
 # One step of RK4
 f1 = rhs_exp(x)
 f2 = rhs_exp(x + 0.5 * tau * f1)
 f3 = rhs_exp(x + 0.5 * tau * f2)
 f4 = rhs_exp(x + tau * f3)

x = x + tau * (f1 + 2*f2 + 2*f3 + f4) /
t = t + tau

Euler VS RK4

Results!

- Percentage error in x(1) after 10 steps:
 - Euler: 4.6% (2)
 - RK4: 0.000077% 😵
- With RK4, the final value is 2.7182797... (e = 2.7182818...)
 - Can we verify the local $O(\tau^5)$?
- ? Why is this kind of unfair?
 - •• 😊 ln each iteration, RK4 makes four RHS evaluations compared to Euler's 1...
 - Euler: 8 RHS calculations (8 steps): 5.6% error.
 - RK4: 8 RHS calculations (2 steps): 0.034% error.

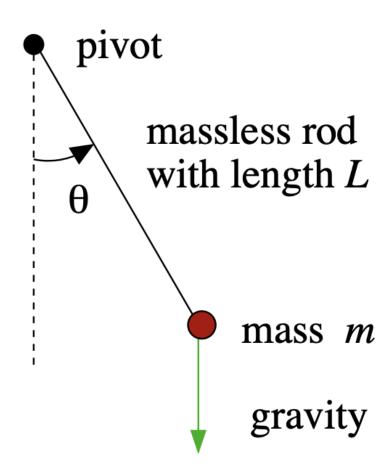

This Week's Problem: The Simple Pendulum

$$ullet rac{d^2 heta}{dt^2} = -rac{g}{L}\sin heta.$$

- angle from the vertical θ , acceleration due to gravity g, length L.
- ?: How might we get this second-order ODE into general form (coupled first-order)?
 - •• Same ole trick: introduce a new variable, ω :

$$rac{d heta}{dt} = \omega\,, \qquad rac{d\omega}{dt} = -rac{g}{L}\sin heta.$$

- Easy, huh? This is the general form, $\frac{d\mathbf{x}}{dt} = \mathbf{f}$
 - $\mathbf{x} = (\theta, \omega)$, $\mathbf{f} = \left(\omega, -\frac{g}{L}\sin\theta\right)$.

- Initial Value Problem: Starting from rest at an angle $heta_1$: $heta(0)= heta_1$ and $\omega(0)=\omega_1=0$.
- This is also a *dynamics* problem.
 - heta is angular position ($r \leftrightarrow heta$).
 - ω is angular speed ($v\leftrightarrow\omega$).
- An approximate analytic solution (valid for $heta_1 \ll 1$) is simple harmonic oscillation: $heta = heta_1 \cos(\Omega t)$,
 - ullet with $\Omega^2=rac{g}{L}$, period $T_0=rac{2\pi}{\Omega}=2\pi\sqrt{rac{L}{g}}$, amplitude $heta_1$.
- For $heta_1 \ll 1$, the period does not depend on amplitude.
 - But the general case is nonlinear, with no simple closed-form analytic solution

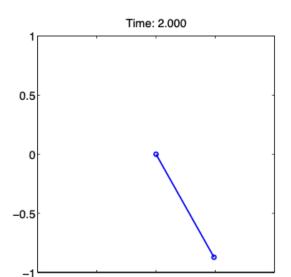

Pendulum: non-dimensionalising

- θ is already non-dimensional
- ullet For time, $ar t=rac{t}{t_s}$, we can set our characteristic timescale, $t_s=T_0=2\pi\sqrt{rac{L}{g}}$:
 - $ullet rac{d^2 heta}{dt^2} = rac{1}{T_0^2} rac{d^2 heta}{dar{t}^2} = rac{g}{4\pi^2 L} rac{d^2 heta}{dar{t}^2}.$
 - $ullet rac{d^2 heta}{dt^2} = -rac{g}{L} \sin heta$ becomes $egin{aligned} rac{d^2 heta}{dar{t}^2} = -4\pi^2\sin heta \end{aligned}$ (no more g or ${\it L}!$)
- ullet This natural timescale, T_0 , yields a non-dimensional period (for $heta \ll 1$), $\overline{T}_0 = rac{T_0}{T_0} = 1$.
- In general form, $\frac{d\mathbf{x}}{dt} = \mathbf{f}$, we have $\mathbf{x} = \begin{pmatrix} \theta \\ \omega \end{pmatrix}$, and $\mathbf{f} = \begin{pmatrix} \omega \\ -4\pi^2 \sin \theta \end{pmatrix}$.

Pendulum problem with RK4

- The general form advantage: we just write down our *RHS function* and let standard numerical methods (like RK) do the rest.
- expproblem_and_simplependulum.ipynb animates the motion of a pendulum.
 - RHS defined in rhs_pend
- Let's play with some different settings
 - Low θ_1 (e.g., 50°) recovers oscillation?
 - ? predictions for $\theta_1 = 180^{\circ}...$?!

? What's this doing?:

```
# One step of RK4
f1 = rhs_pend(x)
f2 = rhs_pend(x + 0.5*tau*f1)
f3 = rhs_pend(x + 0.5*tau*f2)
f4 = rhs_pend(x + tau*f3)
x = x + tau*(f1 + 2*f2 + 2*f3 + f4)/6
```

? What's this doing?:

? What's this doing?:

```
# Update the pendulum position:
# Co-ordinates of the pendulum bar
xPendArray[n+1] = [0, np.sin(x[0])]
yPendArray[n+1] = [0, -np.cos(x[0])]
```

In the tutorial

- You will play with the simple pendulum using pend_rk4 and compare Runge-Kutta to Velocity-Verlet.
- You will adapt an implementation of RK4 to solve the Kepler problem from last week!
 - This may be your biggest challenge yet...
 - If you don't have much experience coding, you can get oneon-one help at the tutorial sessions!
- Next week: We move on to PDEs!
